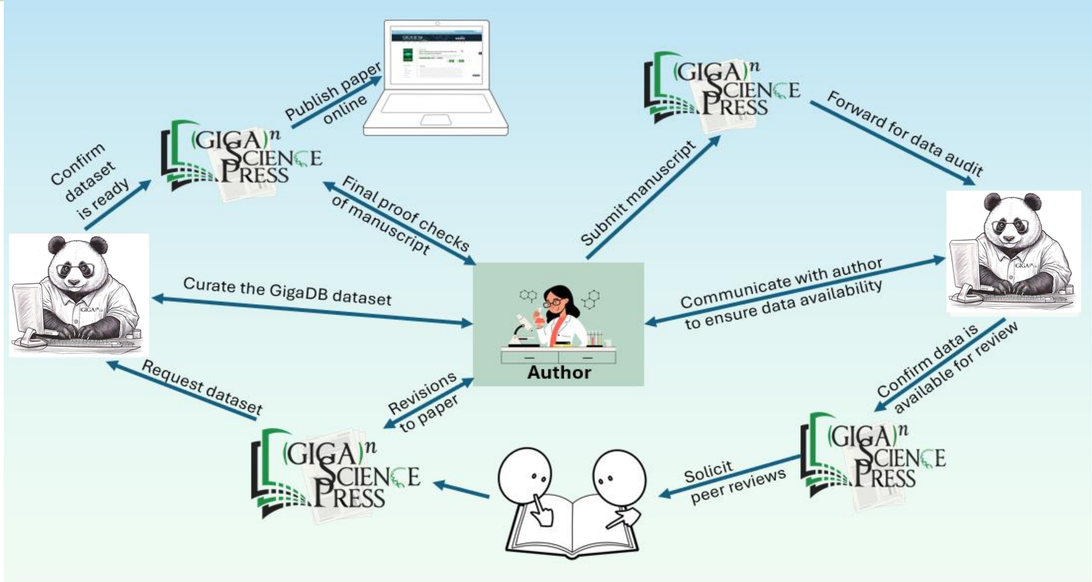
Encouraging authors to use and cite data in public repositories; A publisher perspective

Chris Hunter[1], Bastien Molcrette[1], Yannan Fan[1], Mary Ann Tuli[1]

[1]GigaDB, GigaScience Press, Hong Kong

Introduction

GigaScience Press publishes two journals; *GigaScience* and *GigaByte*, both have extremely high standards for transparency and reproducibility. In order to maintain these standards, we have a team of data curators (biocurators) whose job is to ensure the manuscripts are as transparent and reproducible as possible prior to publication. We have GigaDB, our own repository to host data associated with GigaScience Press articles, however we primarily use that for data that does not have a natural home in a suitable public repository such as the INSDC. GigaDB biocurators act as an interpretation layer between the often-verbose standards of FAIR data, and the time-pressured authors, who require succinct and pertinent guidance specific to their manuscript.



Test your knowledge of the Biocuration ecosystem

Advice and guidance to authors

At the initial stage, the curator provides guidance to authors on which data should be shared and how, as well as assistance with submitting to public repositories. This includes advice on licensing, ethical approval verification, and formatting files for FAIRness.

In the later stage, curators ensure that all input/output data and methodologies are accessible along with their proper annotations, offering support and direction to the authors throughout this process.

Finally, through our partnership with DataCite, each dataset in GigaDB receives a unique Digital Object Identifier (DOI). This allows for standardized citation of these datasets in future research, by both the original authors and other investigators.

Do you recognise these logos? They represent the many of the resources that our authors utilise. We link these resources directly to their GigaDB datasets. Providing these direct links to the relevant data hosted in each of those community resources further enables discovery and reuse of the data.

As an example, for studies involving human clinical data, we check the patient consent form and direct authors toward controlled-access databases, which specialize in hosting sensitive datasets.

For bioinformatics resources, we pay particular attention to the licenses associated with the newly developed resources and we actively work at their integration into any relevant database, providing PIDs (Persistent Identifiers) and thus increasing the FAIRness of these resources.
