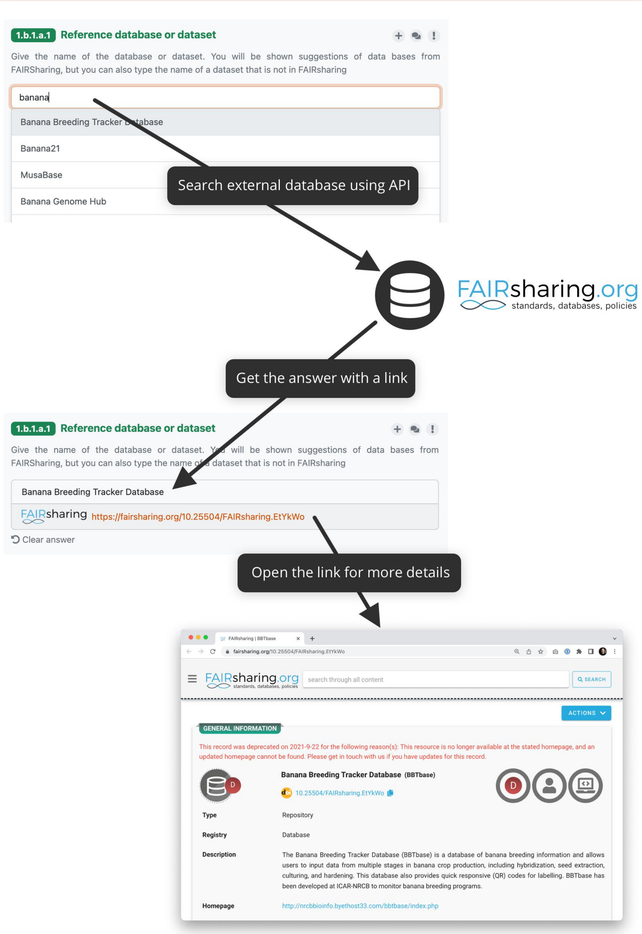
Integration Possibilities of the Data Stewardship Wizard

ds-wizard.org

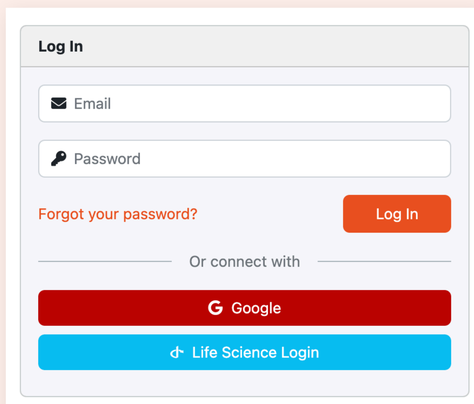
Integrating the DSW with other research-supporting services, databases, or repositories is crucial for streamlining data management processes and saving time. The DSW offers integration possibilities that allow researchers to input information from external resources or databases using integration questions through API or widgets and import data from other tools using project importers. It also provides highly customizable outputs, which enables researchers to export documents in machine-actionable formats that can be further processed. There are also submission services that facilitate data submission to external services.

Integration Question



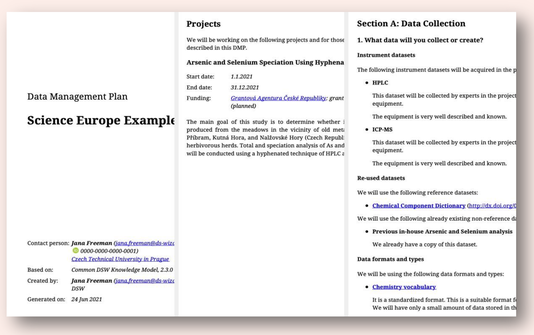
Integration questions can be connected to an external resource using its **API**. We can then search for the results from the external service using the DSW questionnaire interface. When we select an answer, it is not only the text (such as the name of the database) but also a **link to the external service** or **PID** for the selected item.

Single Sign-On



Instead of creating new accounts in DSW, we can connect it to an existing system using the **OpenID** protocol. This enables users to authenticate with their current institutional account directly, or via **Life Science Login**, or also using other existing accounts such as Google.

Document Templates

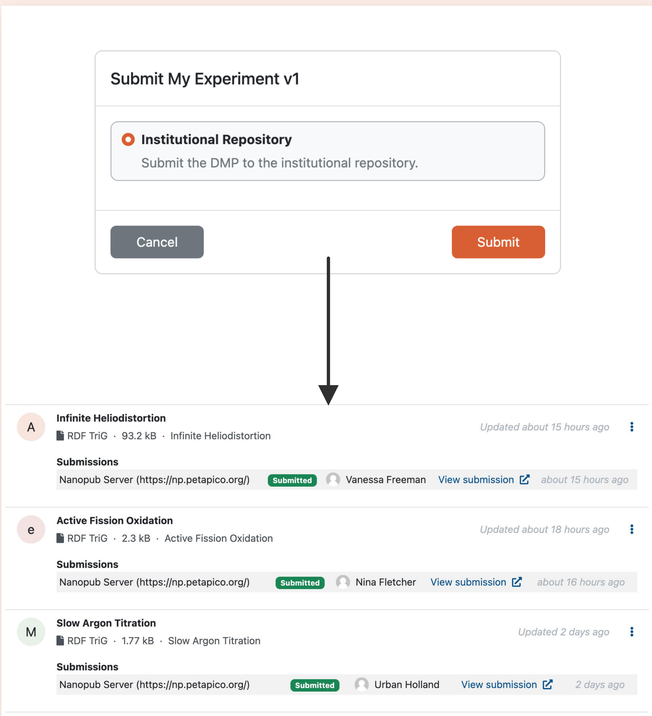


Document templates transform the replies from a questionnaire to a document of a specific format. The document template usually follows some standard defined by a funder or organization, such as **Horizon Europe DMP**, and can support different file formats, such as **PDF** or **MS Word**. The formats can be any text-based format, so it can also be **JSON** or **XML**. Therefore, we can easily use them to create a machine-actionable output, too.

Integration Widget

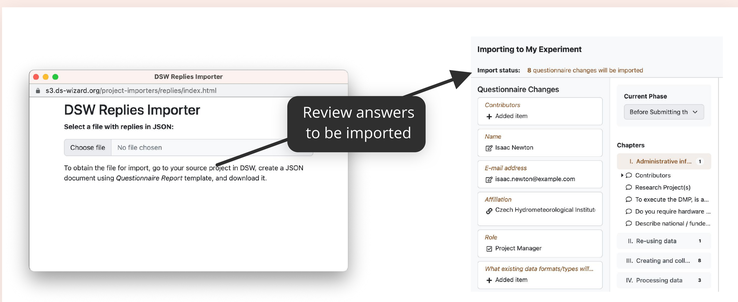
Integration questions can be connected to an external resource using a widget integration. When there is this type of question, instead of writing an answer, researchers open the widget implemented by the **external resource** where they can pick their answer, and it is then sent back to the DSW.

Submission Services



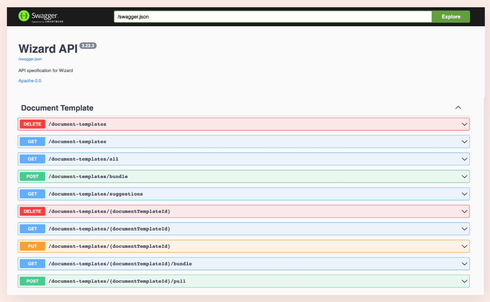
DSW enables the direct submission of documents to external services or databases using the submission service. However, a simple proxy service is typically required to receive **JSON** documents from DSW, gather additional information using **DSW API** (if necessary), and store it in a local database for use by other systems.

Project Importers



Project importers can be used to import data from an external resource to DSW. The importer creates the replies based on the input data and adds them to the questionnaire. The input data can be, for example, from another DSW instance, from different applications, or **maDMP**. Project importers are implemented using a JavaScript library **DSW Importer SDK**, making it possible to create new ones easily.

API



DSW offers an API providing **complete functionality** within the platform. This means that any task that can be accomplished within DSW can also be executed through its API, allowing for a wide range of custom integration with other systems. With the **Swagger** documentation, users can quickly learn how to use the API, making incorporating DSW into existing workflows more streamlined and efficient.
